

Intro to Arduino

A screenshot of the Arduino IDE interface. The left sidebar shows the 'Libraries' panel with a search bar and a list of categories: AUDIO, BRIDGE, EEPROM, ESP8266, and ETHERNET. The main area displays the 'DisplayDriver.ino' code editor with the following code:

```
1 #include <Servo.h>
2 Servo batteria;
3 int tempi[6];
4 int contatore = 0;
5 int metzo = 0;
6 int LedAscolto = 7;
7 int LedSuono = 8;
8 int metroOld = 0;
9 boolean su = false;
10
11 void setup(){
12   Serial.begin(9600);
13   batteria.attach(6);
14   pinMode(LedAscolto, OUTPUT);
15   pinMode(LedSuono, OUTPUT);
16   metzo = millis();
17   /* Comment */
18 }
19 void loop(){
20   digitalWrite(LedAscolto, HIGH);
21   digitalWrite(LedSuono, LOW);
22   while(contatore<6){
23     int toc = analogRead(A0);
24     if(toc<60){
25       Serial.println("Suono numero ");
26       Serial.println(contatore);
27       Serial.print(": ");
28       Serial.println(toc);
29       if(contatore==0){
30         tempi[contatore] = 0;
31       }
32       else{
33         tempi[contatore-1] = millis() - metzo;
34         Serial.print(" Intervallo: ");
35
```

Arduino Microcontroller

- Runs one Program at a time.
- Re-Programmable via USB
- Can run independent of computer (Barrel Jack pwr)
- Reset Button Re-Initiates Program.
- Pins: board inputs + outputs
- Power Pins: Provide Power
- Digital Pins: ON/OFF
- Analog Pins: Spectrum of Input/output values.

Supplying Power & Sending Signals

- In order to power an led or send a signal to the Arduino, you need to complete an electric circuit.
- When you connect a Pin to an LED, it supplies power to the light, but only if the other end is connected to a GND (ground pin).
- This completes the circuit, like connecting a light to both terminals of a battery.

Voltage, Current, Resistance

$$V = I * R$$

Voltage: 'Power' supplied to component.

Resistance: Resists, or 'Consumes' Voltage. An LED is also a Resistor.

Current: Can be thought of as the 'Bandwidth' of the circuit. If you have a lot of different circuits pulling from the same voltage source, it will reduce the power, *like having too many computers connected to the same wifi.*

For more in-depth explanation, see:

<https://learn.sparkfun.com/tutorials/voltage-current-resistance-and-ohms-law>

Components and Orientation

For Certain Components, the direction of the current flow is important, for others it isn't.

(-) = GND

(+) = PWR

LEDs: Directional (Polarized)

Resistors: Non-Directional
(Non-Polarized)

Tip: If a component is symmetrical, then it is probably Non-Polarized. If there are asymmetric markings or geometry, then it might be Polarized.

The Breadboard: Make Connections without Soldering

Rows are Connected (12345...)

Columns are Not (abcde....)

(except power rails, which are connected vertically)

The Code: Basic Structure

- **Setup**

{Only Runs Once. Tell Arduino what pins you want to use, give them names, etc.}

- **Loop**

{Runs Continuously. Tell Arduino what pins to turn on/off, what inputs to look for, etc.}

- **Today:** Use Example Code, make small changes, see how the Arduino Responds. Pay attention to structure and keywords (will be colored).

Curious about a term? Look it up in the Arduino Reference Library:
